

Two purples

	
#6D4AFF · in your system	#6F4DFA · in the new design

A new token, or the same purple picked by eye?

Get it wrong often enough and nobody knows which grey is the good one.

The model never answers that

Every value is sorted before a line of the component is written.

String equality would create a second
neutral-900.

exact

already in the system, used as is

ΔE 0

near

the system's value wins, drift reported

$\Delta E \leq 1 \cdot \#6F4DFA \rightarrow 0.79$

new

another colour: it needs a name, a person
decides

$\#7B5CFF \rightarrow 5.00$

CIEDE2000 $\cdot 1.0$ = just noticeable, trained eye

It asked me to name a token I already had

I was comparing composites as text. A border is a width, a style and a colour, and a design system holds those apart — so comparing the whole string finds nothing.

```
new token needed: 1px solid #9aa3ad
```

1px	already in the scale
solid	not a token at all
#9aa3ad	already a colour in the config

On one real run, three of the four tokens it proposed were compositions of values the project already had. The rot the feature exists to prevent, produced by the feature.

Now a composite is read as parts.

80 values

Last full page I measured, twelve sections:

65

already in the system

7

nudged into it, drift reported

8

needed a name — asked once, for the whole page
